

ABSTRACT

A chamber (12) having an approximately triangular transverse cross section is provided with a gas supply opening (13) at its one side, and is provided with an exhaust opening (14) at a vertex facing the one side. Further, the gas supply opening (13) is
5 provided with a showerhead-like gas supply section (15). Based on this configuration, the chamber (12) is structured such that a cross-sectional area S of a gas flow passage formed from the gas supply opening (13) to the exhaust opening (14) gradually decreases toward a direction of gas supply (x direction). At this time, a thickness δ of a boundary layer (28) formed on a wall of the chamber (12) becomes substantially constant.
